

Hello Team leader,

After exploratory analysis of the JSON files for receipts, users, and brands data, the following observations were made:

- The receipts file contains nested JSONs specifically the rewardsReceiptItemList column, is possible to have the rewardsReceiptItemList column expanded into a separable table?
- In the user's JSON file, the _id column is the unique identifier of the table; however, the table contains duplicated values for the _id column. Can a primary key be placed on the table to prevent the creation of duplicated accounts for the same user?
- The data contains lots of null values, how should they be handled? Is it possible to include a not-null constraint in some of the columns?
- Where and how are the JSON files created?

I need a little help with this information so that better improvements can be made to the system.

Best Regards,

Ehimwenma Omoregbee
